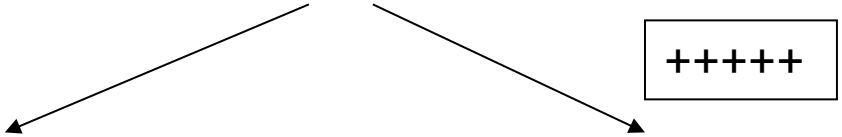
Multidrug-Resistant Bacterial Organisms Causing Major Clinical Problems.*

Organism and Antibiotic Resistance	Common Mechanism of Resistance	Recent, Resurrected, and Future Antimicrobial Agents with Potential Clinical Use
Hospital-associated MRSA†		
Vancomycin (both VISA and VRSA)	Thickening of cell wall (not fully elucidated); change in the last amino acid of peptidoglycan precursors	Linezolid, quinupristin–dalfopristin, daptomycin, tigecycline, ceftobiprole, ceftaroline, dalbavancin, telavancin, oritavancin, iclaprim
Daptomycin	Associated with changes in cell wall and cell membrane (not fully elucidated)	Linezolid, quinupristin–dalfopristin, tigecycline, ceftobiprole, ceftaroline, dalbavancin, telavancin, oritavancin, iclaprim
Linezolid	Mutations in the 23S ribosomal RNA genes; rarely, acquisition of a methyltransferase gene (*cfr*)	Daptomycin, quinupristin–dalfopristin, tigecycline, ceftobiprole, ceftaroline, dalbavancin, telavancin, oritavancin, iclaprim
Vancomycin-resistant *Enterococcus faecium*‡		
Ampicillin (common)	Mutation and overexpression of *pbp5*	Linezolid, quinupristin–dalfopristin, daptomycin, tigecycline
High-level resistance to aminoglycosides	Acquisition of aminoglycoside-modifying enzymes; ribosomal mutations (streptomycin)	No alternative for a reliable bactericidal effect alone or in combination
Linezolid	Mutations in the 23S ribosomal RNA genes	Quinupristin–dalfopristin, daptomycin, tigecycline
Daptomycin	Unknown	Linezolid, quinupristin–dalfopristin, tigecycline
Quinupristin–dalfopristin	Enzymes that inactivate quinupristin–dalfopristin, target modification	Daptomycin, linezolid, tigecycline
Escherichia coli, klebsiella species, and enterobacter species§		
Oxyimino-cephalosporins (ceftriaxone, cefotaxime, ceftazidime, and cefepime)	Extended-spectrum β-lactamases (includes hyperproduction of the AmpC enzymes by Enterobacteriaceae family)	Carbapenems, tigecycline
Carbapenems	Production of carbapenemases, decreased permeability	Polymyxins, tigecycline
Acinetobacter species¶		
Carbapenems	Decreased permeability, increased efflux, and production of carbapenemases	Polymyxins
Pseudomonas aeruginosa¶		
Carbapenems	Decreased permeability, increased efflux, and production of carbapenemases	Polymyxins

Mécanisme d'émergences de résistances



- **Direct :** Émergence de résistance au site infectieux
  - **Une seule espèce**
  - **Faible nombre de bactéries**
  - **Ne touche que les patients réellement infectés**
  - **Un seul mécanisme de résistance**

- **Indirecte :** émergence de résistance au niveau de la flore commensale (cutanée, digestive)
  - **Plusieurs espèces**
  - **Grand nombre de bactéries**
  - **Mécanismes de résistance multiple**
  - **Touche tous les patients mêmes non traités**

Moyens de lutte

- Réduire **le nombre de prescription** ! Ex : campagne « les ATB c'est pas automatique »
- Réduire **la durée de prescription**
- Mais **ne pas réduire la dose**: moindre efficacité>>persistance de l'agent pathogène>>développement de résistance

En pratique

- 10 pts X 10 j = 100 DDJ
- 8 pts X 10j = 80 DDJ
- 10 pts X 8 j = 80 DDJ aussi…!
- Les 20% de DDJ « gagnées » ne sont peut-être pas équivalentes…

D’après Pr Antoine Andremont, Laboratoire de bactéiologie, CHU Claude Bernard Bichat Paris 7

Effets des volumes de consommation d'ATB sur la résistance bactérienne

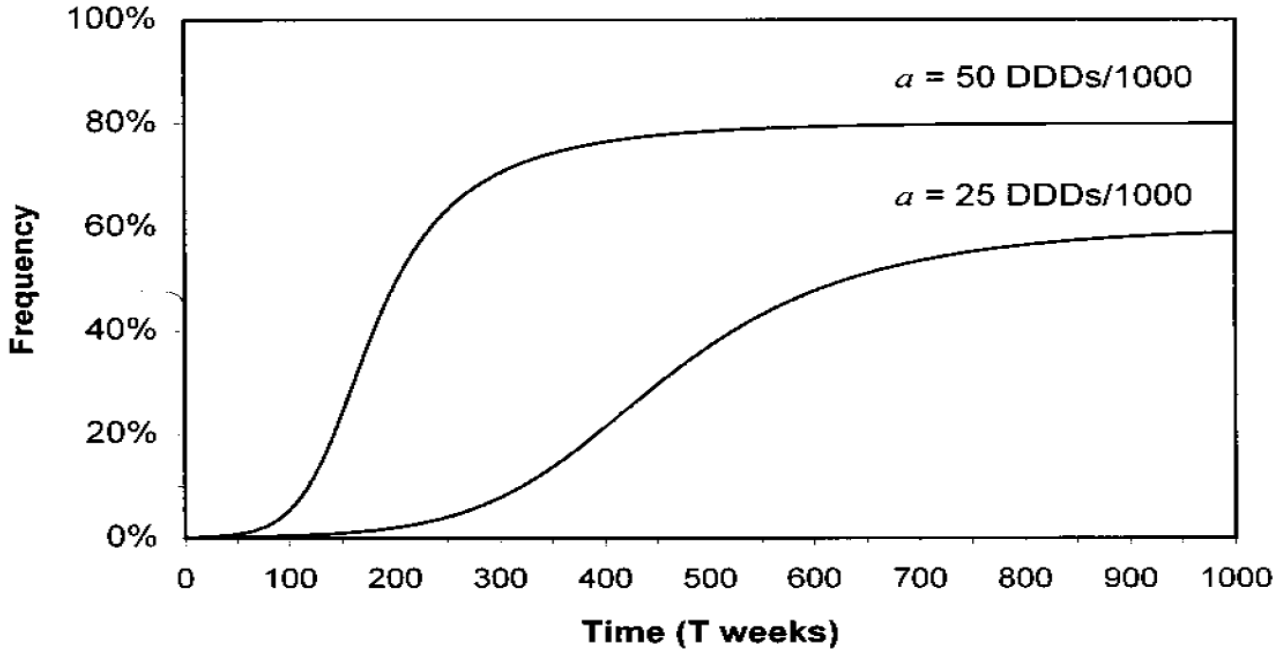


FIG. 1. Change in the frequency of resistance p_t after frequency-dependent selection in which antibiotic consumption falls as resistance rises ($w_S(q_t) = 1 - aq_t$, $w_R = 0.99$, and $p_0 = 10^{-3}$).

Rubinstein E. Int J Antimicrob Agents. 2007 Nov;30 Suppl 1:S76-9

MISE AU POINT

Antibiothérapie par voie générale dans les infections respiratoires basses de l'adulte
Pneumonie aiguë communautaire
Exacerbations de Bronchopneumopathie Chronique Obstructive

« La durée de traitement antibiotique des PAC est classiquement de 7 à 14 jours (10 jours en moyenne) »

IDSA/ATS guidelines (Mandell et al. CID 2007)

Patients with CAP should be treated for a minimum of **5 days**.
The recommended duration for patients with **good clinical response** within the first 2-3 d of therapy is 5 to 7 days total

NICE recommendations :
5 day course of antibiotic therapy for patients with low severity CAP;
Consider a **7-10** day course of antibiotic therapy for patients with moderate **and high severity** CAP.

DUREE DE TRAITEMENT DES PNEUMONIES COMMUNAUTAIRES

Organisation	Durée recommandée de traitement
IDSA 2003	***S.pneumoniae* : tt poursuivi 72 h après apyrexie** ***S.aureus, P.aeruginosa*, K.sp, anaérobies et bactéries atypiques : Tt ≥ 2 semaines**
CIDS / CTS 2000	**1 à 2 semaines, selon la réponse du patient**
ATS 2001	***S.pneumoniae* et autres bactéries: 7-10 jours** **Atypiques: Tt peut nécessiter 10 à 14 jours** **Nouveaux ATB peuvent raccourcir à 5-7 jours pour patients ambulatoires**
BTS 2001	**Pathogène non identifié: 7-10 jours** **Legionella sp: 14-21 jours** **Atypiques: 14 jours** **S.pneumoniae: 7 jours** **Staph, entérobactéries: 14-21 jours**

DUREE DE TRAITEMENT DES PNEUMONIES COMMUNAUTAIRES

Organisation	Durée recommandée de traitement
IDSA / ATS 2007	Durée de Tt minimale: 5 jours (niveau de preuve I), apyrexie depuis 48 à 72 h et pas plus d'un signe d'instabilité avant arrêt du tt (niveau de preuve II). (recommandation modérée)
ERS / ESCMID 2005	Durée appropriée non établie Durée habituelle 7 à 10 jours (sécurité inconnue pour des durées inférieures) Bactéries intra cellulaires comme *L.pneumophila*: au moins 14 jours. (grade C4)
SPILF 2006	La durée classique du traitement est de 7 à 14 jours (10 jours en moyenne). Les nouvelles molécules (kétolides, FQ anti pneumococciques) permettent de diminuer cette durée.

Should Patients With VAP Receive 7 Days or 8–15 Days of Antibiotic Therapy? Recommendation

- For patients with VAP, we recommend a 7-day course of antimicrobial therapy rather than a longer duration (strong recommendation, moderate-quality evidence).

- Remarks: There exist situations in which a shorter or longer duration of antibiotics may be indicated, depending upon the rate of improvement of clinical, radiologic, and laboratory parameters.

One-day treatment for lobar pneumonia

D. R. SUTTON, A. C. B. WICKS, and LINDSAY DAVIDSON

Department of Medicine, University College of Rhodesia

An investigation was undertaken to discover whether a single intramuscular dose of long-acting (or mixed long-acting and crystalline) penicillin or a single day's therapy with oral penicillin was satisfactory treatment for lobar pneumonia. These treatments were compared with standard hospital oral and injection therapies. All the experimental treatment regimes were found to be satisfactory. They provide justification for treating lobar pneumonia on an out-patient basis in order to save hospital admissions.

Short-course versus prolonged-course antibiotic therapy for hospital-acquired pneumonia in critically ill adults (Review)

Pugh R, Grant C, Cooke RPD, Dempsey G

Authors' conclusions

We conclude that for patients with VAP not due to NF-GNB, a short fixed-course (seven or eight days) antibiotic therapy may be more appropriate than a prolonged course (10 to 15 days). Use of an individualised strategy (incorporating clinical features or serum procalcitonin) appears to safely reduce duration of antibiotic therapy for VAP.

HAS (avril 2008)

- « L'antibiothérapie curative ne dépasse généralement pas **une semaine**.
- En effet, beaucoup d'infections ne nécessitent pas une antibiothérapie d'une durée plus longue.
- Une antibiothérapie prolongée expose à un bénéfice/risque défavorable (résistances bactériennes augmentées, toxicité accrue).
- De plus, des traitements plus courts ont été validés dans des situations bien définies. »

Context The optimal duration of antimicrobial treatment for ventilator-associated pneumonia (VAP) is unknown. Shortening the length of treatment may help to contain the emergence of multiresistant bacteria in the intensive care unit (ICU).

Objective To determine whether 8 days is as effective as 15 days of antibiotic treatment of patients with microbiologically proven VAP.

Design, Setting, and Participants Prospective, randomized, double-blind (until day 8) clinical trial conducted in 51 French ICUs. A total of 401 patients diagnosed as having developed VAP by quantitative culture results of bronchoscopic specimens and who had received initial appropriate empirical antimicrobial therapy were enrolled between May 1999 and June 2002.

Intervention A total of 197 patients were randomly assigned to receive 8 days and 204 to receive 15 days of therapy with an antibiotic regimen selected by the treating physician.

Main Outcome Measures Primary outcome measures—death from any cause, microbiologically documented pulmonary infection recurrence, and antibiotic-free days—were assessed 28 days after VAP onset and analyzed on an intent-to-treat basis.

Results Compared with patients treated for 15 days, those treated for 8 days had neither excess mortality (18.8% vs 17.2%; difference, 1.6%; 90% confidence interval [CI], −3.7% to 6.9%) nor more recurrent infections (28.9% vs 26.0%; difference

Outcome

PHRC national 12-202.0496

- **Hypothèse** : antibiothérapie de 3 jours est suffisante chez les patients avec une PAC répondant à 3 jours de C3G ou amoxicilline-acide clavulanique

- **Méthode** :
  - Essai multicentrique (20 centres),
  - Contrôlé, randomisé vs placebo (double aveugle)
  - De non infériorité,
  - 2 groupes parallèles,
  - Comparant 2 durées de traitement : 3j *vs.* 8j

Critères d'inclusion

- **Age > 18 ans**
- Ayant consulté en urgence 3 jours avant
- **Admis pour PAC**

J0
  - **1 des signes** : dyspnée, toux, exp. muco-pur., foyer de crépitants
  - \+ T> **38**°C
  - \+ Nouvel **infiltrat** à la RX

- **Ayant répondu à 3 jours de TT** par C3G ou amox-clav.

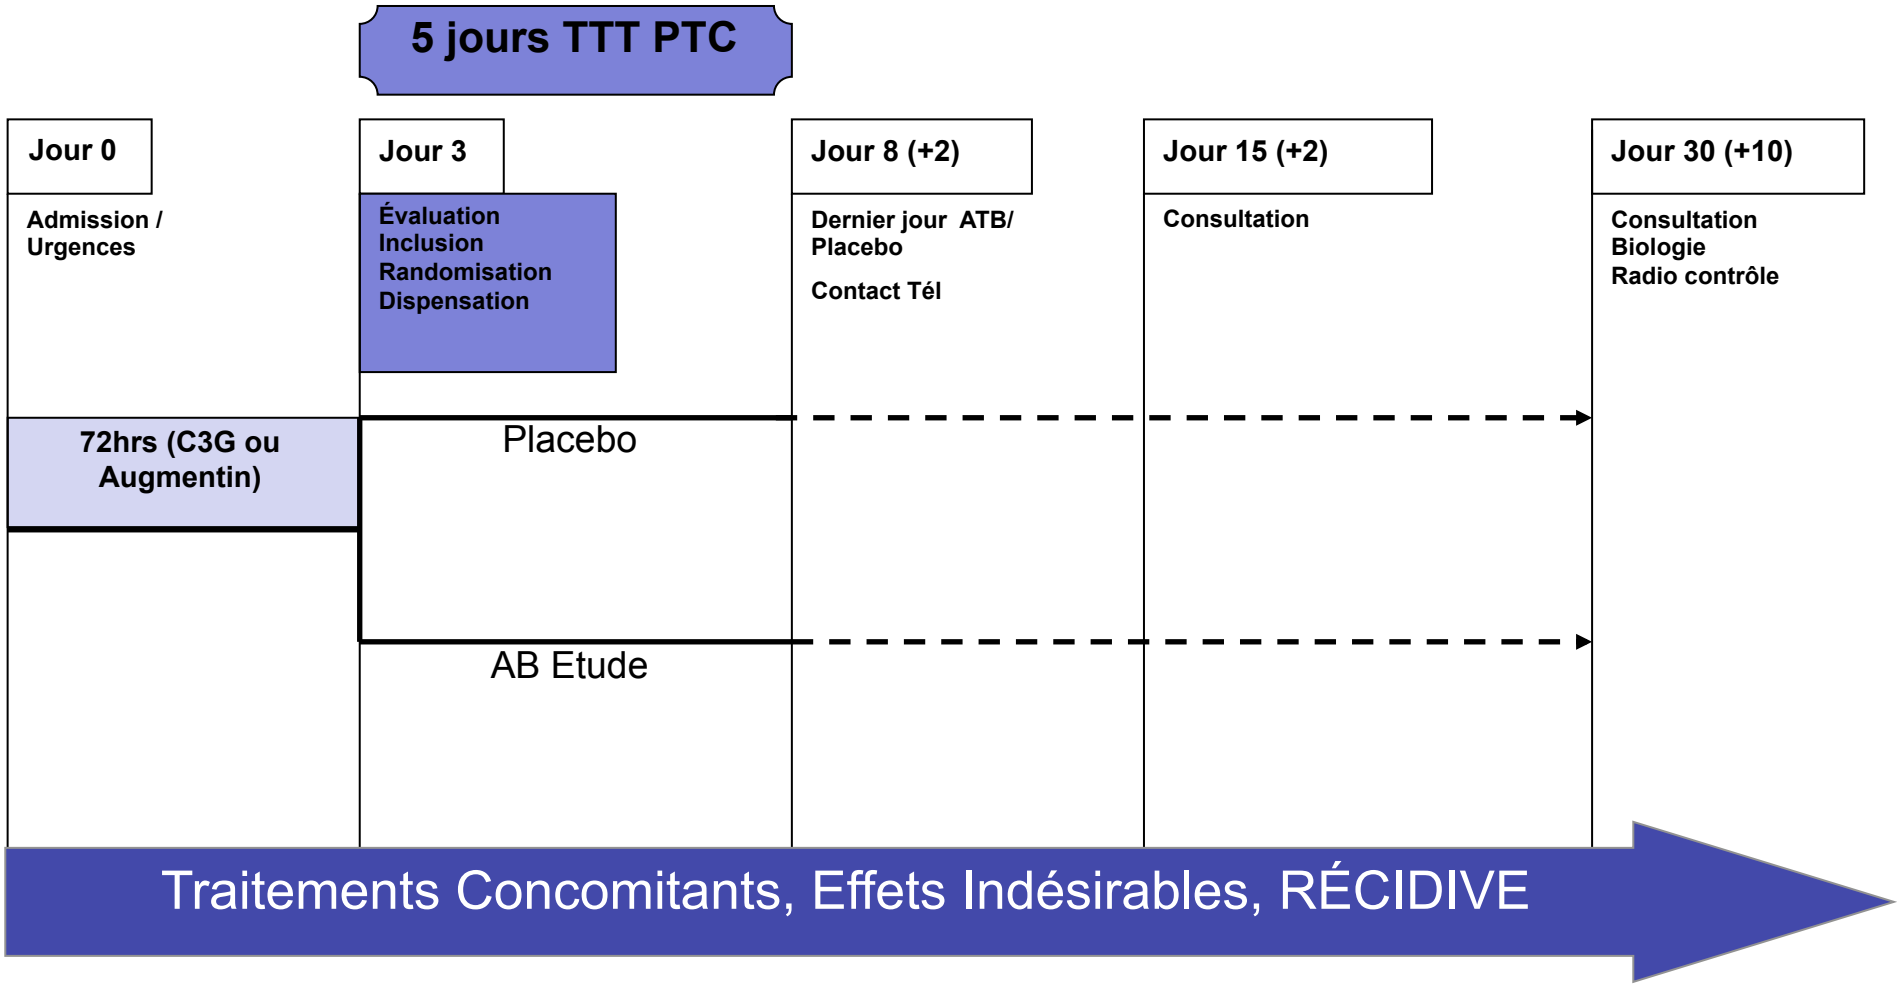
J3
  - T ≤ 37,8°C
  - \+ Critères de stabilité IDSA
    - FC < 100/min et
    - FR < 24c/min)
    - SaO2 ≥ 90% (mode oxygénation normale préalable PAC)
    - Pa Systolique ≥ 90 mmHg

- Apte à prendre un traitement oral

Critères de non inclusion

- PAC sévère ou compliquée
- Légionellose suspectée ou confirmée
- Pneumonies liées aux soins
- Suspicion de pneumopathie d'inhalation
- Infection intercurrente requérant un traitement antibiotique
- Terrain immunodéprimé connu
- Antibiothérapie préalable de plus de 24 h avant la consultation aux urgences
- Bithérapie (1 dose de macrolides ou de FQ autorisée)
- Clairance de la créatinine < à 30ml/min
- Antécédents d'ictères/Atteinte hépatique liés à l'amox/ac.clav
- Antécédent d'hypersensibilité à une β-lactamine
- Femmes enceintes
- Allaitement
- Espérance de vie < 1 mois
- Patient sous tutelle ou sans couverture sociale
- Personnes sans domicile fixe

Schéma de l'étude



Critère de jugement principal

- **Guérison** définie à J15 par association de :
  - Apyrexie (température corporelle < 37,8°C)
  - Disparition ou amélioration des signes cliniques suivants s'ils étaient initialement présents :
    - dyspnée,
    - toux,
    - expectorations muco-purulentes,
    - foyer de crépitants
  - Sans antibiothérapie additionnelle depuis J8

Objectifs secondaires

- Comparer **l'efficacité clinique à J30**
- Comparer la **survenue d'EI** lié au traitement antibiotique
- Comparer la **durée d'hospitalisation**
- Comparer la **satisfaction globale** des patients à J30
- Comparer la **reprise de l'activité** professionnelle et des activités habituelles à J30

Résultats (1/2)

- Aujourd'hui (30/11) : **284 inclusions**
- Patients : âge moy 68.5 ±18.8 ans, sexe ratio 1.5 (M/F)
- Principaux antécédents :

Principales comorbidités	**%**
BPCO	24
Insuffisance cardiaque	21
Diabète	20
Maladie vasculaire cérébrale	9
Pathologie rénale	6
Néoplasie	2
Pathologie hépatique	2

Résultats (2/2)

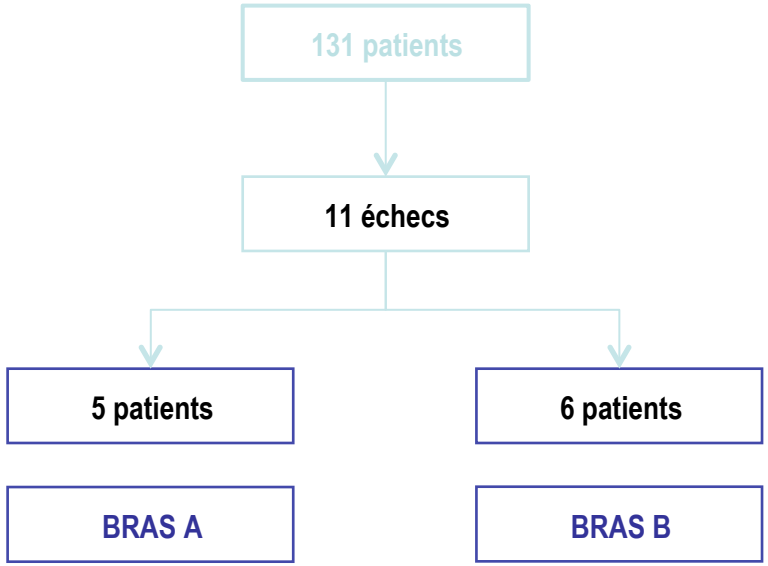
- Durée moyenne séjour : 6,2 jours
- Principal évènement indésirable : diarrhées (n=24), dont 1 infection à *Clostridium difficile*
- **33 EIG** (18 patients), **3 décès**.

Evènements indésirables graves	**N**
Récidive pneumonie	14
Superinfection	2
Insuffisance cardiaque	3
Néoplasie	2
Infection intercurrente	2
Allergie	2
VIH	I

Evènements indésirables graves	**N**
AVC	I
Deshydratation	I
Hépatite	1
Péricardite	1
Crise d'asthme	1
Douleurs lombaires	1
Lithiase rénale	1

Comité Indépendant de Surveillance

- Révision des 131 premiers patients inclus : 19 ont présenté un EIG et 3 sont décédés.
- Taux de guérison global : 91,6%
  - avec 11 échecs dont 2 décès,
  - répartis entre les deux bras de l'étude (6/5).
- Le comité indépendant a conclu à la sécurité de l'essai et à sa poursuite.



Discussion

- Population **âgée avec comorbidités** correspondant aux données de la littérature (PAC hospitalisés)
- 3j *vs* 8j : R. El Moussaoui *et al.* (BMJ 2006) >> patients **jeunes,** PAC **peu grave**
- PAC **bactérienne ?**
- Rapidité de la **réponse au traitement** antibiotique : élément essentiel pronostique de la durée nécessaire

Conclusion

EDITORIAL

The New Antibiotic Mantra—"Shorter Is Better"

Brad Spellberg, MD

Of course, the ultimate goal is to customize duration of therapy to the patient's response. So what should we do when patients are given a prescription for a fixed duration of therapy and their symptoms resolve before they complete the course?

Here we need to change the dogma: patients should no longer be told to keep taking the antibiotic. Patients should be told that if their symptoms resolve before completing the antibiotic they should communicate with their physician to determine if they can stop therapy early. Health care professionals should be encouraged to allow patients to stop antibiotic treatment as early as possible on resolution of symptoms of infection. Ultimately, we should replace the old dogma of continuing therapy past resolution of symptoms with a new, evidence-based dogma of "shorter is better."

REVIEW

Corticosteroid Therapy for Patients Hospitalized With Community-Acquired Pneumonia

A Systematic Review and Meta-analysis

Background: Community-acquired pneumonia (CAP) is common and often severe.

Purpose: To examine the effect of adjunctive corticosteroid therapy on mortality, morbidity, and duration of hospitalization in patients with CAP.

Data Sources: MEDLINE, EMBASE, and the Cochrane Central Register of Controlled Trials through 24 May 2015.

Study Selection: Randomized trials of systemic corticosteroids in hospitalized adults with CAP.

Data Extraction: Two reviewers independently extracted study data and assessed risk of bias. Quality of evidence was assessed with the Grading of Recommendations Assessment, Development and Evaluation system by consensus among the authors.

Data Synthesis: The median age was typically in the 60s, and approximately 60% of patients were male. Adjunctive corticosteroids were associated with possible reductions in all-cause mortality (12 trials; 1974 patients; risk ratio [RR], 0.67 [95% CI, 0.45 to 1.01]; risk difference [RD], 2.8%; moderate certainty), need for mechanical ventilation (5 trials; 1060 patients; RR, 0.45 [CI, 0.26 to 0.79]; RD, 5.0%; moderate certainty), and the acute respiratory distress syndrome (4 trials; 945 patients; RR, 0.24 [CI, 0.10 to 0.56]; RD, 6.2%; moderate certainty). They also decreased time to clinical stability (5 trials; 1180 patients; mean difference, −1.22 days [CI, −2.08 to −0.35 days]; high certainty) and duration of hospitalization (6 trials; 1499 patients; mean difference, −1.00 day [CI, −1.79 to −0.21 days]; high certainty). Adjunctive corticosteroids increased frequency of hyperglycemia requiring treatment (6 trials; 1534 patients; RR, 1.49 [CI, 1.01 to 2.19]; RD, 3.5%; high certainty) but did not increase frequency of gastrointestinal hemorrhage.

Limitations: There were few events and trials for many outcomes. Trials often excluded patients at high risk for adverse events.

Conclusion: For hospitalized adults with CAP, systemic corticosteroid therapy may reduce mortality by approximately 3%, need for mechanical ventilation by approximately 5%, and hospital stay by approximately 1 day.

Primary Funding Source: None.

Adjunct prednisone therapy for patients with community-acquired pneumonia: a multicentre, double-blind, randomised, placebo-controlled trial

Summary

Background Clinical trials yielded conflicting data about the benefit of adding systemic corticosteroids for treatment of community-acquired pneumonia. We assessed whether short-term corticosteroid treatment reduces time to clinical stability in patients admitted to hospital for community-acquired pneumonia.

Methods In this double-blind, multicentre, randomised, placebo-controlled trial, we recruited patients aged 18 years or older with community-acquired pneumonia from seven tertiary care hospitals in Switzerland within 24 h of presentation. Patients were randomly assigned (1:1 ratio) to receive either prednisone 50 mg daily for 7 days or placebo. The computer-generated randomisation was done with variable block sizes of four to six and stratified by study centre. The primary endpoint was time to clinical stability defined as time (days) until stable vital signs for at least 24 h, and analysed by intention to treat. This trial is registered with ClinicalTrials.gov, number NCT00973154.

Findings From Dec 1, 2009, to May 21, 2014, of 2911 patients assessed for eligibility, 785 patients were randomly assigned to either the prednisone group (n=392) or the placebo group (n=393). Median time to clinical stability was shorter in the prednisone group (3·0 days, IQR 2·5–3·4) than in the placebo group (4·4 days, 4·0–5·0; hazard ratio [HR] 1·33, 95% CI 1·15–1·50, p<0·0001). Pneumonia-associated complications until day 30 did not differ between groups (11 [3%] in the prednisone group and 22 [6%] in the placebo group; odds ratio [OR] 0·49 [95% CI 0·23–1·02]; p=0·056). The prednisone group had a higher incidence of in-hospital hyperglycaemia needing insulin treatment (76 [19%] *vs* 43 [11%]; OR 1·96, 95% CI 1·31–2·93, p=0·0010). Other adverse events compatible with corticosteroid use were rare and similar in both groups.

Interpretation Prednisone treatment for 7 days in patients with community-acquired pneumonia admitted to hospital shortens time to clinical stability without an increase in complications. This finding is relevant from a patient perspective and an important determinant of hospital costs and efficiency.

Antibiotic Treatment Strategies for Community-Acquired Pneumonia in Adults

Douwe F. Postma, M.D., Cornelis H. van Werkhoven, M.D., Leontine J.R. van Elden, M.D., Ph.D., Steven F.T. Thijsen, M.D., Ph.D., Andy I.M. Hoepelman, M.D., Ph.D., Jan A.J.W. Kluytmans, M.D., Ph.D., Wim G. Boersma, M.D., Ph.D., Clara J. Compaijen, M.D., Eva van der Wall, M.D Jan M. Prins, M.D., Ph.D., Jan J. Oosterheert, M.D., Ph.D., and Marc J.M. Bonten, M.D., Ph.D., for the CAP-START Study Group*

BACKGROUND

The choice of empirical antibiotic treatment for patients with clinically suspected community-acquired pneumonia (CAP) who are admitted to non–intensive care unit (ICU) hospital wards is complicated by the limited availability of evidence. We compared strategies of empirical treatment (allowing deviations for medical reasons) with beta-lactam monotherapy, beta-lactam–macrolide combination therapy, or fluoroquinolone monotherapy.

METHODS

In a cluster-randomized, crossover trial with strategies rotated in 4-month periods, we tested the noninferiority of the beta-lactam strategy to the beta-lactam–macrolide and fluoroquinolone strategies with respect to 90-day mortality, in an intention-to-treat analysis, using a noninferiority margin of 3 percentage points and a two-sided 90% confidence interval.

RESULTS

A total of 656 patients were included during the beta-lactam strategy periods, 739 during the beta-lactam–macrolide strategy periods, and 888 during the fluoroquinolone strategy periods, with rates of adherence to the strategy of 93.0%, 88.0%, and 92.7%, respectively. The median age of the patients was 70 years. The crude 90-day mortality was 9.0% (59 patients), 11.1% (82 patients), and 8.8% (78 patients), respectively, during these strategy periods. In the intention-to-treat analysis, the risk of death was higher by 1.9 percentage points (90% confidence interval [CI], −0.6 to 4.4) with the beta-lactam–macrolide strategy than with the beta-lactam strategy and lower by 0.6 percentage points (90% CI, −2.8 to 1.9) with the fluoroquinolone strategy than with the beta-lactam strategy. These results indicated noninferiority of the beta-lactam strategy. The median length of hospital stay was 6 days for all strategies, and the median time to starting oral treatment was 3 days (interquartile range, 0 to 4) with the fluoroquinolone strategy and 4 days (interquartile range, 3 to 5) with the other strategies.

CONCLUSIONS

Among patients with clinically suspected CAP admitted to non-ICU wards, a strategy of preferred empirical treatment with beta-lactam monotherapy was noninferior to strategies with a beta-lactam–macrolide combination or fluoroquinolone monotherapy with regard to 90-day mortality. Table 1. Definitions.

Case definitions

Community-acquired pneumonia (CAP) (working diagnosis): The presence of at least two of the diagnostic clinical criteria and in-hospital treatment with antibiotics for clinically suspected CAP as documented by the treating physician. Patients with two or more criteria and an obvious nonrespiratory source of infection were not considered to have a working diagnosis of CAP, nor were patients who had recently been hospitalized (for >48 hours in the previous 2 weeks) or who resided in long-term care facilities.

Radiologically confirmed CAP: A working diagnosis of CAP plus the presence of a new or increased infiltrate on chest radiography or computed tomography (CT) and at least two other clinical criteria.

Diagnostic clinical criteria

Cough

Production of purulent sputum or a change in the character of sputum

Temperature >38°C or <36.1°C

Auscultatory findings consistent with pneumonia, including rales, evidence of pulmonary consolidation (dullness on percussion, bronchial breath sounds, or egophony), or both

Leukocytosis (>10×10^9 white cells per liter or >15% bands)

C-reactive protein level more than 3 times the upper limit of the normal range

Dyspnea, tachypnea, or hypoxemia

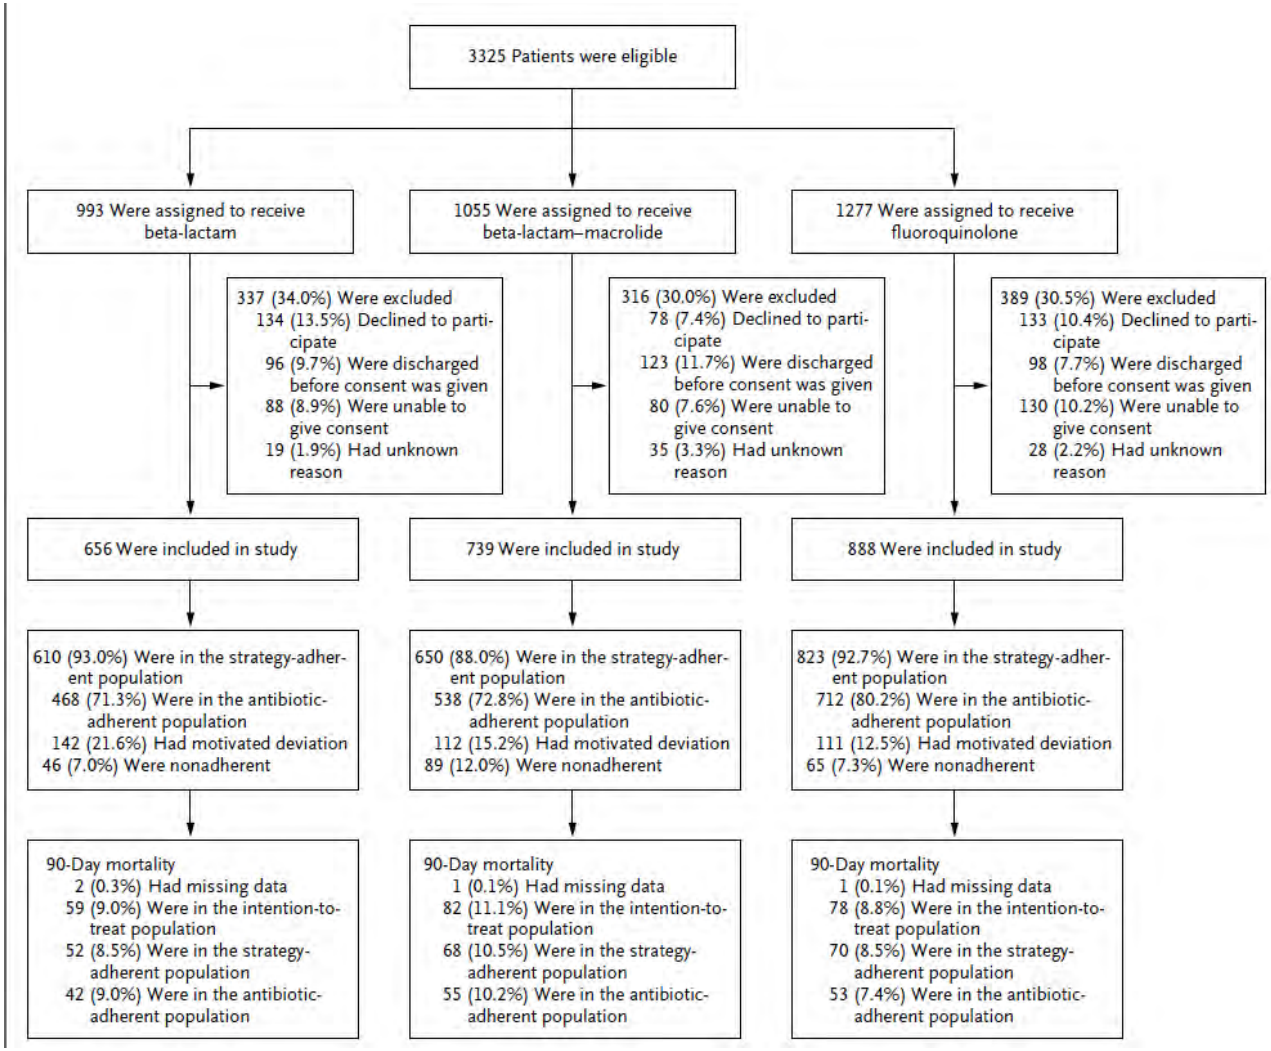
New or increased infiltrate on chest radiography or CT scan

Intervention strategies*

Beta-lactam strategy: Preferred empirical treatment with amoxicillin, amoxicillin plus clavulanate, or a third-generation cephalosporin. Penicillin was not allowed as empirical beta-lactam monotherapy.

Beta-lactam–macrolide strategy: Preferred empirical treatment with penicillin, amoxicillin, amoxicillin plus clavulanate, or a third-generation cephalosporin in combination with azithromycin, erythromycin, or clarithromycin

Fluoroquinolone strategy: Preferred empirical treatment with moxifloxacin or levofloxacin



3325 Patients were eligible
993 Were assigned to receive beta-lactam
1055 Were assigned to receive beta-lactam–macrolide
1277 Were assigned to receive fluoroquinolone
337 (34.0%) Were excluded
134 (13.5%) Declined to participate

Original Investigation

β-Lactam Monotherapy vs β-Lactam–Macrolide Combination Treatment in Moderately Severe Community-Acquired Pneumonia

A Randomized Noninferiority Trial

Nicolas Garin, MD; Daniel Genné, MD; Sebastian Carballo, MD, DPhil; Christian Chuard, MD; Gerhardt Eich, MD; Olivier Hugli, MD, MPH; Olivier Lamy, MD; Mathieu Nendaz, MD, MHPE; Pierre-Auguste Petignat, MD; Thomas Perneger, MD, PhD; Olivier Rutschmann, MD, MPH; Laurent Seravalli, MD; Stephan Harbarth, MD, MS; Arnaud Perrier, MD

IMPORTANCE The clinical benefit of adding a macrolide to a β-lactam for empirical treatment of moderately severe community-acquired pneumonia remains controversial.

OBJECTIVE To test noninferiority of a β-lactam alone compared with a β-lactam and macrolide combination in moderately severe community-acquired pneumonia.

DESIGN, SETTING, AND PARTICIPANTS Open-label, multicenter, noninferiority, randomized trial conducted from January 13, 2009, through January 31, 2013, in 580 immunocompetent adult patients hospitalized in 6 acute care hospitals in Switzerland for moderately severe community-acquired pneumonia. Follow-up extended to 90 days. Outcome assessors were masked to treatment allocation.

INTERVENTIONS Patients were treated with a β-lactam and a macrolide (combination arm) or with a β-lactam alone (monotherapy arm). *Legionella pneumophila* infection was systematically searched and treated by addition of a macrolide to the monotherapy arm.

MAIN OUTCOMES AND MEASURES Proportion of patients not reaching clinical stability (heart rate <100/min, systolic blood pressure >90 mm Hg, temperature <38.0°C, respiratory rate <24/min, and oxygen saturation >90% on room air) at day 7.

RESULTS After 7 days of treatment, 120 of 291 patients (41.2%) in the monotherapy arm vs 97 of 289 (33.6%) in the combination arm had not reached clinical stability (7.6% difference, $P = .07$). The upper limit of the 1-sided 90% CI was 13.0%, exceeding the predefined noninferiority boundary of 8%. Patients infected with atypical pathogens (hazard ratio [HR], 0.33; 95% CI, 0.13-0.85) or with Pneumonia Severity Index (PSI) category IV pneumonia (HR, 0.81; 95% CI, 0.59-1.10) were less likely to reach clinical stability with monotherapy, whereas patients not infected with atypical pathogens (HR, 0.99; 95% CI, 0.80-1.22) or with PSI category I to III pneumonia (HR, 1.06; 95% CI, 0.82-1.36) had equivalent outcomes in the 2 arms. There were more 30-day readmissions in the monotherapy arm (7.9% vs 3.1%, $P = .01$). Mortality, intensive care unit admission, complications, length of stay, and recurrence of pneumonia within 90 days did not differ between the 2 arms.

CONCLUSIONS AND RELEVANCE We did not find noninferiority of β-lactam monotherapy in patients hospitalized for moderately severe community-acquired pneumonia. Patients infected with atypical pathogens or with PSI category IV pneumonia had delayed clinical stability with monotherapy.

TRIAL REGISTRATION clinicaltrials.gov Identifier: NCT00818610

Risk factors for 30-day mortality in patients with pneumonia who receive appropriate initial antibiotics: an observational cohort study

Yuichiro Shindo, Ryota Ito, Daisuke Kobayashi, Masahiko Ando, Motoshi Ichikawa, Yasuhiro Goto, Yasutaka Fukui, Mai Iwaki, Junya Okumura, Ikuo Yamaguchi, Tetsuya Yagi, Yoshimasa Tanikawa, Yasuteru Sugino, Joe Shindoh, Tomohiko Ogasawara, Fumio Nomura, Hideo Saka, Masashi Yamamoto, Hiroyuki Taniguchi, Ryujiro Suzuki, Hiroshi Saito, Takashi Kawamura, Yoshinori Hasegawa, on behalf of the Central Japan Lung Study Group

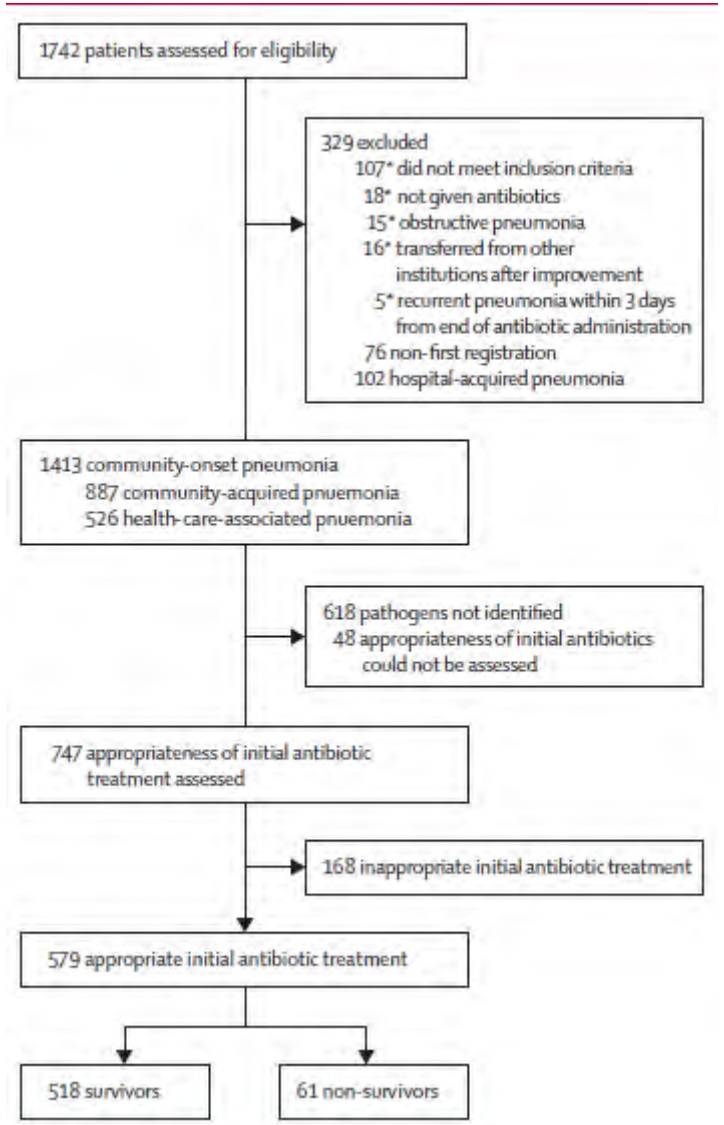
Summary

Background Appropriate initial antibiotics are essential for the treatment of infectious diseases. However, some patients with pneumonia might develop adverse outcomes, despite receiving appropriate initial antibiotics. We aimed to clarify the risk factors for 30-day mortality in patients who received appropriate initial antibiotics and to identify potential candidates who would benefit from adjunctive therapy.

Methods From March 15, to Dec 22, 2010, we did a prospective, observational study at ten medical institutions in hospitalised patients (aged ≥20 years) with pneumonia. We did a multivariable logistic regression analysis to calculate odds ratios (ORs) and 95% CI to assess the risk factors for 30-day mortality. This study was registered with the University Medical Information Network in Japan, number UMIN000003306.

Findings The 30-day mortality was 11% (61 of 579 patients) in the appropriate initial antibiotic treatment group and 17% (29 of 168) in the inappropriate initial antibiotic treatment group. Albumin concentration of less than 30 mg/L (adjusted OR 3·39, 95% CI 1·83–6·28), non-ambulatory status (3·34, 1·84–6·05), pH of less than 7·35 (3·13, 1·52–6·42), respiration rate of at least 30 breaths per min (2·33, 1·28–4·24), and blood urea nitrogen of at least 7·14 mmol/L (2·20, 1·13–4·30) were independent risk factors in patients given appropriate initial antibiotic treatment. The 30-day mortality was 1% (one of 126 patients), 1% (two of 168), 17% (23 of 137), 22% (20 of 89), and 44% (14 of 32) for patients with no, one, two, three, and four or five risk factors, respectively.

Interpretation Patients with two or more risk factors were at a higher risk of death during the 30 days assessed than were individuals with no or one risk factor, despite appropriate initial antibiotic treatment. Therefore, adjunctive therapy might be important for improving outcomes in patients with two or more risk factors.



1742 patients assessed for eligibility
329 excluded
107* did not meet inclusion criteria

Effect of Corticosteroids on Treatment Failure Among Hospitalized Patients With Severe Community-Acquired Pneumonia and High Inflammatory Response

A Randomized Clinical Trial

Antoni Torres, MD, PhD; Oriol Sibila, MD, PhD; Miquel Ferrer, MD, PhD; Eva Polverino, MD, PhD; Rosario Menendez, MD, PhD; Josep Mensa, MD, PhD; Albert Gabarrús, MSc; Jacobo Sellarés, MD, PhD; Marcos I. Restrepo, MD, MSc; Antonio Anzueto, MD, PhD; Michael S. Niederman, MD; Carles Agustí, MD, PhD

IMPORTANCE In patients with severe community-acquired pneumonia, treatment failure is associated with excessive inflammatory response and worse outcomes. Corticosteroids may modulate cytokine release in these patients, but the benefit of this adjunctive therapy remains controversial.

OBJECTIVE To assess the effect of corticosteroids in patients with severe community-acquired pneumonia and high associated inflammatory response.

DESIGN, SETTING, AND PARTICIPANTS Multicenter, randomized, double-blind, placebo-controlled trial conducted in 3 Spanish teaching hospitals involving patients with both severe community-acquired pneumonia and a high inflammatory response, which was defined as a level of C-reactive protein greater than 150 mg/L at admission. Patients were recruited and followed up from June 2004 through February 2012.

INTERVENTIONS Patients were randomized to receive either an intravenous bolus of 0.5 mg/kg per 12 hours of methylprednisolone (n = 61) or placebo (n = 59) for 5 days started within 36 hours of hospital admission.

MAIN OUTCOMES AND MEASURES The primary outcome was treatment failure (composite outcome of early treatment failure defined as [1] clinical deterioration indicated by development of shock, [2] need for invasive mechanical ventilation not present at baseline, or [3] death within 72 hours of treatment; or composite outcome of late treatment failure defined as [1] radiographic progression, [2] persistence of severe respiratory failure, [3] development of shock, [4] need for invasive mechanical ventilation not present at baseline, or [5] death between 72 hours and 120 hours after treatment initiation; or both early and late treatment failure). In-hospital mortality was a secondary outcome and adverse events were assessed.

RESULTS There was less treatment failure among patients from the methylprednisolone group (8 patients [13%]) compared with the placebo group (18 patients [31%]) (P = .02), with a difference between groups of 18% (95% CI, 3% to 32%). Corticosteroid treatment reduced the risk of treatment failure (odds ratio, 0.34 [95% CI, 0.14 to 0.87]; P = .02). In-hospital mortality did not differ between the 2 groups (6 patients [10%] in the methylprednisolone group vs 9 patients [15%] in the placebo group; P = .37); the difference between groups was 5% (95% CI, −6% to 17%). Hyperglycemia occurred in 11 patients (18%) in the methylprednisolone group and in 7 patients (12%) in the placebo group (P = .34).

CONCLUSIONS AND RELEVANCE Among patients with severe community-acquired pneumonia and high initial inflammatory response, the acute use of methylprednisolone compared with placebo decreased treatment failure. If replicated, these findings would support the use of corticosteroids as adjunctive treatment in this clinical population.

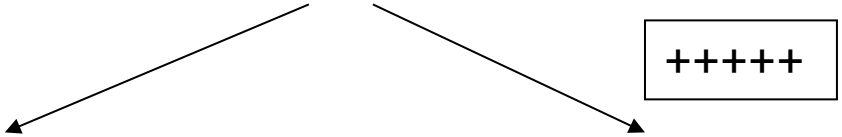
Multidrug-Resistant Bacterial Organisms Causing Major Clinical Problems.*

Organism and Antibiotic Resistance	Common Mechanism of Resistance	Recent, Resurrected, and Future Antimicrobial Agents with Potential Clinical Use
Hospital-associated MRSA†		
Vancomycin (both VISA and VRSA)	Thickening of cell wall (not fully elucidated); change in the last amino acid of peptidoglycan precursors	Linezolid, quinupristin–dalfopristin, daptomycin, tigecycline, ceftobiprole, ceftaroline, dalbavancin, telavancin, oritavancin, iclaprim
Daptomycin	Associated with changes in cell wall and cell membrane (not fully elucidated)	Linezolid, quinupristin–dalfopristin, tigecycline, ceftobiprole, ceftaroline, dalbavancin, telavancin, oritavancin, iclaprim
Linezolid	Mutations in the 23S ribosomal RNA genes; rarely, acquisition of a methyltransferase gene (*cfr*)	Daptomycin, quinupristin–dalfopristin, tigecycline, ceftobiprole, ceftaroline, dalbavancin, telavancin, oritavancin, iclaprim
Vancomycin-resistant *Enterococcus faecium*‡		
Ampicillin (common)	Mutation and overexpression of *pbp5*	Linezolid, quinupristin–dalfopristin, daptomycin, tigecycline
High-level resistance to aminoglycosides	Acquisition of aminoglycoside-modifying enzymes; ribosomal mutations (streptomycin)	No alternative for a reliable bactericidal effect alone or in combination
Linezolid	Mutations in the 23S ribosomal RNA genes	Quinupristin–dalfopristin, daptomycin, tigecycline
Daptomycin	Unknown	Linezolid, quinupristin–dalfopristin, tigecycline
Quinupristin–dalfopristin	Enzymes that inactivate quinupristin–dalfopristin, target modification	Daptomycin, linezolid, tigecycline
Escherichia coli, klebsiella species, and enterobacter species§		
Oxyimino-cephalosporins (ceftriaxone, cefotaxime, ceftazidime, and cefepime)	Extended-spectrum β-lactamases (includes hyperproduction of the AmpC enzymes by Enterobacteriaceae family)	Carbapenems, tigecycline
Carbapenems	Production of carbapenemases, decreased permeability	Polymyxins, tigecycline
Acinetobacter species¶		
Carbapenems	Decreased permeability, increased efflux, and production of carbapenemases	Polymyxins
Pseudomonas aeruginosa¶		
Carbapenems	Decreased permeability, increased efflux, and production of carbapenemases	Polymyxins

Mécanisme d'émergences de résistances



- **Direct :** Émergence de résistance au site infectieux
  - **Une seule espèce**
  - **Faible nombre de bactéries**
  - **Ne touche que les patients réellement infectés**
  - **Un seul mécanisme de résistance**

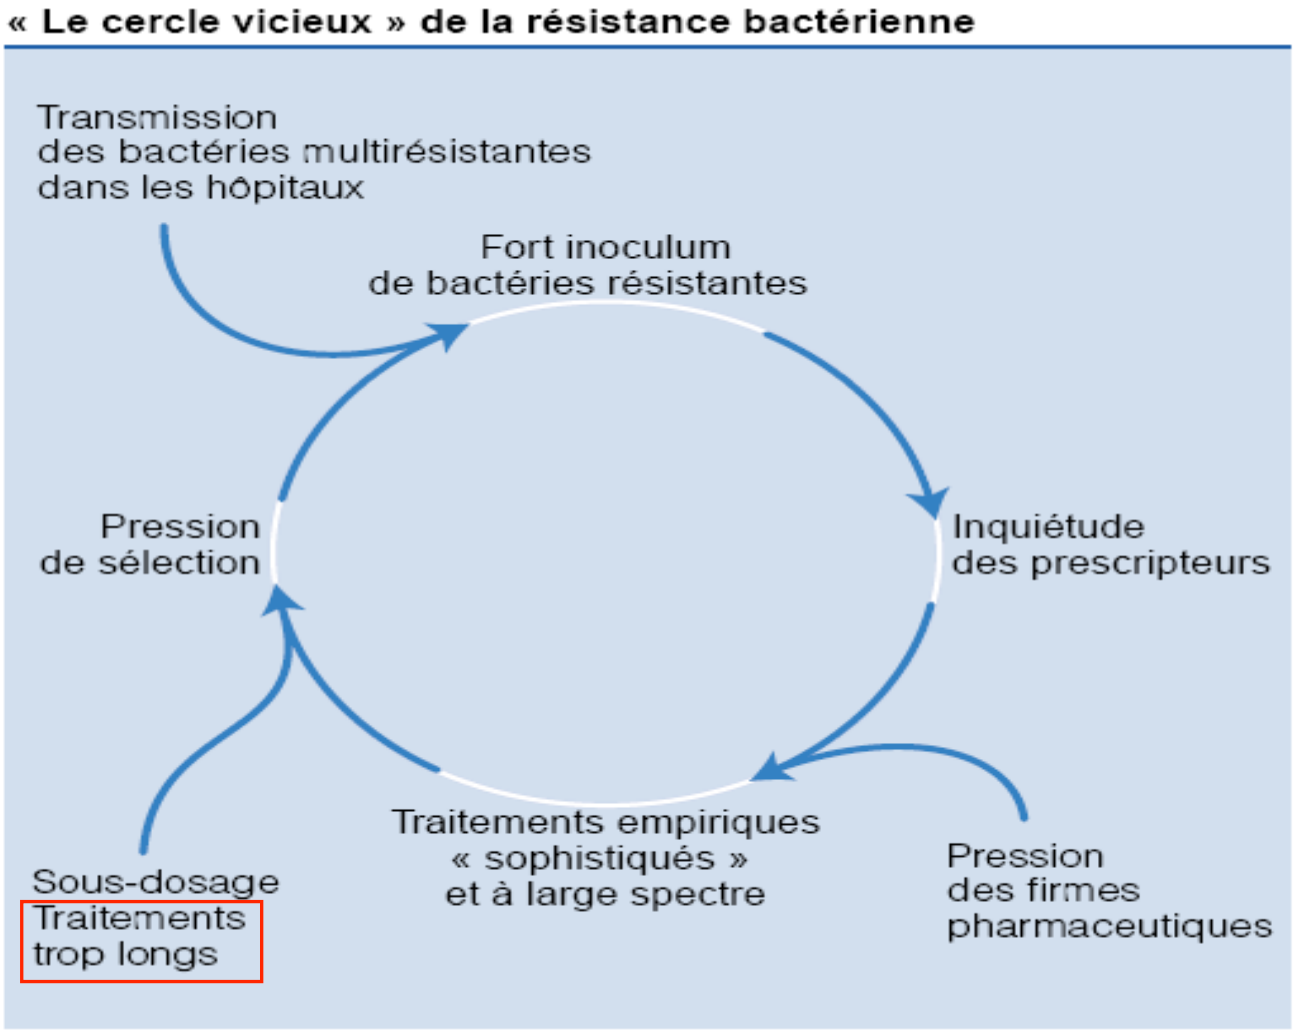
- **Indirecte :** émergence de résistance au niveau de la flore commensale (cutanée, digestive)
  - **Plusieurs espèces**
  - **Grand nombre de bactéries**
  - **Mécanismes de résistance multiple**
  - **Touche tous les patients mêmes non traités**

Rationnel

- 48h d'ATB >> modification des flores digestives et cutanées avec augmentation de la proportion de la résistance bactérienne (Korinek, Ann fr anesth rea 2000).
- Flore commensale contribue à la dissémination des gènes de résistance aux antibiotiques (AC Crémieux, AAC 2003)
- La quantité d'ATB prescrite est liée au taux de résistance bactérienne (Goossens H. Lancet 2005, Schrag SJ JAMA 2001)

Impact sur les flores commensales

Cercle vicieux de la résistance

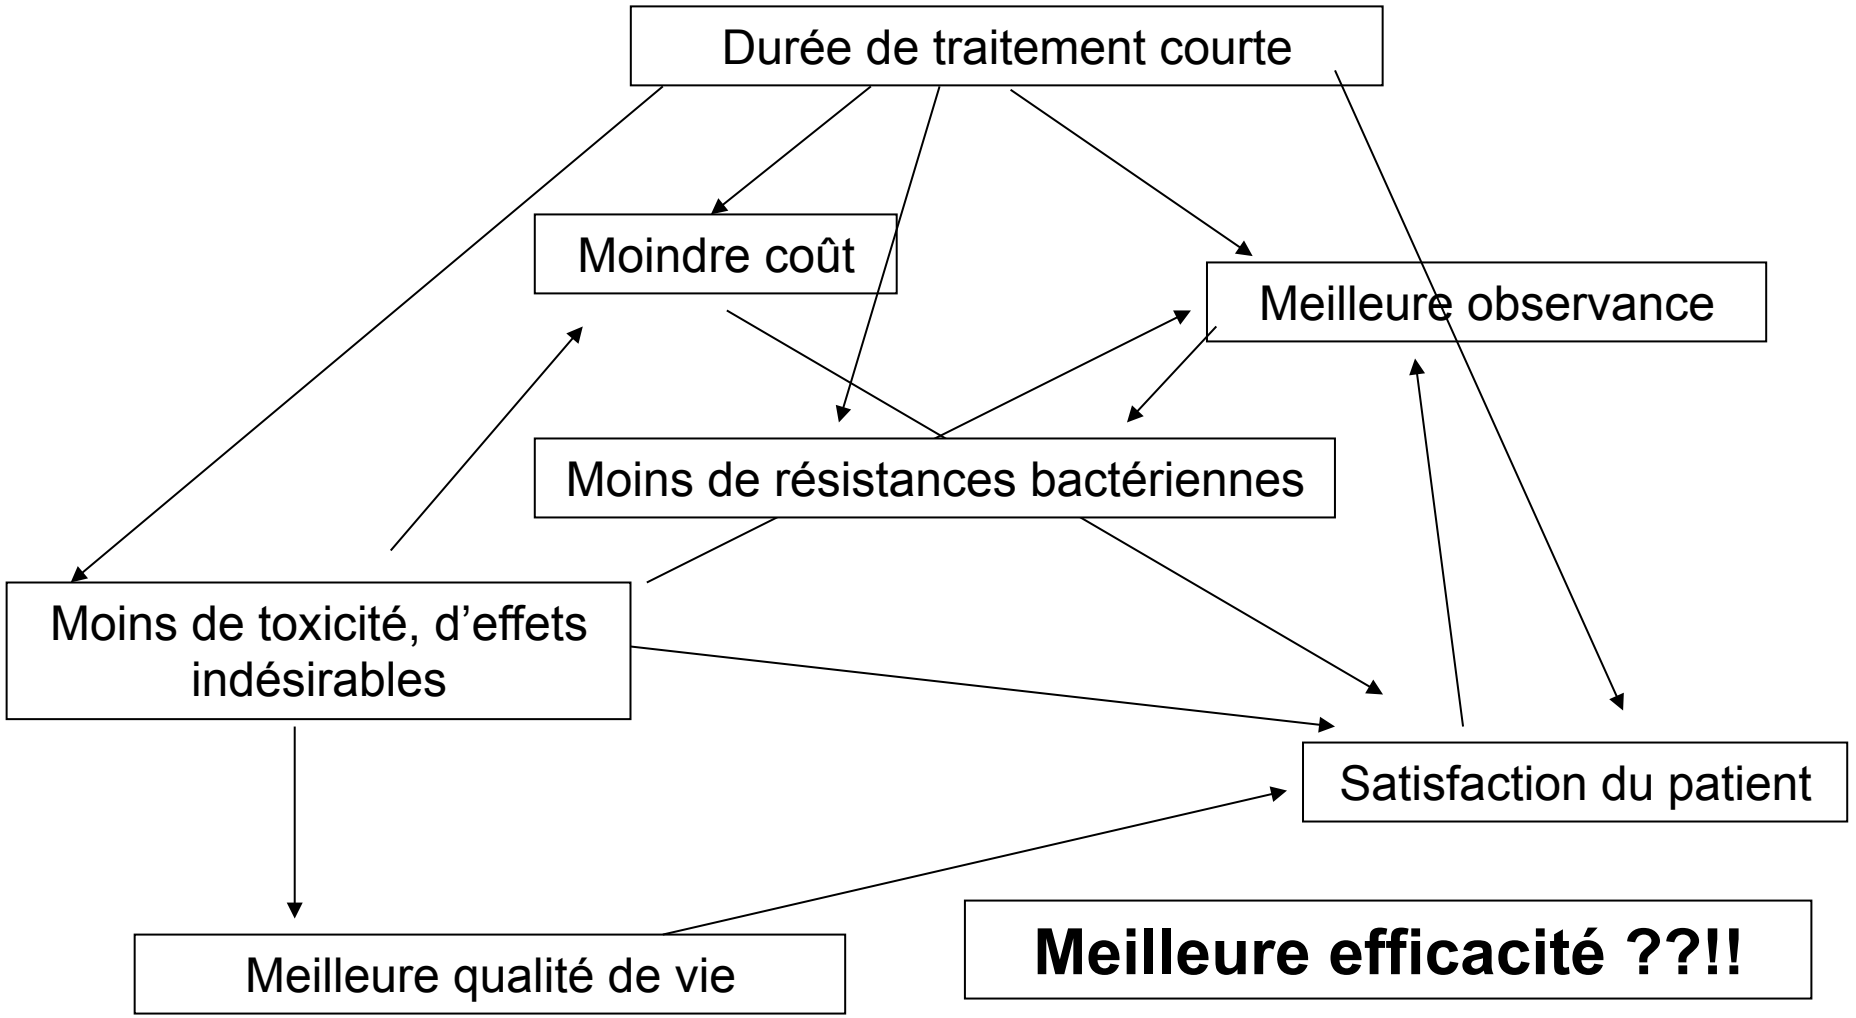


D'après Jean Carlet

Traitements courts ou prolongés

- Traitement **prolongé** bien établi pour
  - Infections à Staphylocoque doré,
  - Endocardite,
  - IOA
- Traitement **court** bien établi pour
  - Prophylaxie chirurgicale,
  - IST (Gonococcie),
  - IU basse
- Surprenant manque de preuve en faveur de TTT courts pour des **infections fréquentes** (PNA, PNP, DHD…)

Intérêt d'une durée courte pour une même efficacité !!



D'après Li JZ. Am Med J 2007

Effets indésirables de l'antibiothérapie

Flore digestive

- C2G et C3G >> modifications rapides mais transitoires de la flore digestive
- traitement 5 à 10 jours : diarrhée
  - chez 17,5 % des adultes, (<2j dans 2/3 des cas)
  - chez 11 % des enfants

a Withdrawals due to adverse events or another disease.

EOT = end of therapy; **FU** = follow-up; **LC** = long course; **NR** = not reported; **pt** = patient; **SC** = short course.

Coût de l’antibiothérapie

The Cost of Treating Community-Acquired Pneumonia

Michael S. Niederman, MD,[1] Jeffrey S. McCombs, PhD,[2] Alan N. Unger, PhD,[3] Amit Kumar, MD,[3] and Robert Popovian, MS, PharmD[4]

Table V. Drug costs as fraction of total hospital costs for Medicare patients (≥65 years) with community-acquired pneumonia.

Department	Average Charge	Average Cost	% of Cost
Drugs	$2424	$873*	12.2
All others	$10,148	$6293†	87.8
Total	$12,572	$7166	100.0

Data from Medicare Standard Analytical File Part A total charges and drug charges.
*Deflated by drug department cost-to-charge ratio.
†Deflated by overall hospital average cost-to-charge ratio.

Table X. Antibiotic drug costs as percentage of total outpatient costs.

Visit Site	Outpatient Costs (in millions of dollars) Excluding Drug Costs	Antibiotic Drug Costs	Total Costs	Antibiotic Drug Costs as Percentage of Total
Office	223.260	29.814	253.074	11.8
Emergency department	96.143	26.338	122.481	21.5
Outpatient clinic	32.563	3.577	36.140	9.9
Other (skilled nursing facility, nursing home, etc)	32.502	4.340*	36.842	11.8
Total	384.468	64.069	448.537	14.3

Data from National Ambulatory Medical Care Survey[12] and National Hospital Ambulatory Medical Care Survey[13]; drug visits times average drug costs.

*Since direct estimates of drug usage and costs were not available for this category, drug costs were assumed to constitute the same share of total costs as for office visits.

Comment définir la durée d'un traitement antibiotique ?

- **Largement fondée sur des données empiriques**
- **Guérison difficile à affirmer ,**
  - **possibilité de rechute tardive de certaines infections,**
  - **Intérêt des scores clinico biologiques ?**
- **Exprimée le plus souvent sous la forme d'une fourchette**
- **Rarement mentionnée dans l'AMM des antibiotiques**
- **Sources : ouvrages médicaux (PILLY , POPI , GENetPi …) ,**
- **Conférences de Consensus , Recommandations AFSSAPS , Conférences d'Experts**
- **Essais cliniques (peu nombreux)**

Histoire de traitement ex de la PNA

	1ère apparition	Résistance	R aujourd'hui	Durée de traitement
Sulfamides	1950	1958	30%	42 j
Acide Nalidixique	1965	1974	20%	
Cotrimoxazole	1974	1979	15-30%	
Amoxicilline	1974	1977	35-45%	42 j
A-AC	1978	1983	20-25%	
Ceftriaxone	1981	1986	<2%	10-14 j
Fluoroquinolones	1986	1992	2-7%	5-7 j

Revue des données concernant des Pneumopathies

Conclusion

- Il y a une place pour les traitements courts dans les PAC !
- Reste à définir la population concernée
- Jusqu'où « descendre » ?
- Bien évaluer ces traitements afin d'éviter un recours « sauvage »
- Donc nécessité de nouvelles études (difficultés méthodologiques)

Comment y arriver ?

- Conseil/intervention pharmacien, informatique…/cours, formation
- Essai randomisé de durée de traitement
- Biomarqueurs : PCT ?

Table 3. Clinical Success Rates at Days 10 and 30 Among Different Severity Groups Defined by PSI Class[a]

PSI Class	No. (%) of Participants		*P* Value
	Control Group	Intervention Group	
Clinical Success at Day 10			
PSI classes I-III			
Intent to treat	41/86 (47.7)	58/101 (57.4)	.18
Per protocol	39/80 (48.8)	58/94 (61.7)	.09
PSI classes IV-V			
Intent to treat	30/60 (50)	32/59 (54.2)	.64
Per protocol	28/53 (52.8)	28/50 (56)	.75
Clinical Success at Day 30			
PSI classes I-III			
Intent to treat	83/88 (94.3)	93/102 (91.2)	.41
Per protocol	80/82 (97.6)	89/95 (93.7)	.29
PSI classes IV-V			
Intent to treat	49/61 (80.3)	54/58 (93.1)	.04
Per protocol	46/54 (85.2)	47/49 (95.9)	.10

Questions (2)

- Back office ?
- Données centralisées transmises directement et surveillance (TEC)>> données manquantes
- Alertes :
  - Prise médicamenteuse >> compliance
  - Arrêt traitement >> durée adaptée
  - Aggravation >> avis médical (réglementaire)

Contexte

- **Résistance bactérienne** : incidence croissante = enjeu de santé publique mondial
- PAC : **infections bactériennes** les plus **fréquentes** et 1ère cause de prescriptions d'antibiotiques
- **Durée de traitement** antibiotique des PAC :
  - Non standardisée
  - Recommandations variables
  - Pas de preuves univoques
- **Diminution de la durée de traitement** → diminution de la durée d'hospitalisation, de l'incidence des effets indésirables, des coûts.

Conclusions

CLINICAL SIGNIFICANCE

- Adults with mild-moderate community-acquired pneumonia can be effectively treated with an antibiotic regimen of 7 days or less.
- This result is consistent among the 4 antibiotic classes studied (macrolide, fluoroquinolone, beta-lactam, and ketolide).
- There is a trend toward decreased adverse events with antibiotic regimens of 7 days or less.
